AUTHOR: Kiselev A.N., Guards Maj

TITLE: Flight Discipline (Distsiplina poleta)

PERIODICAL: Vestnik Vozdushnogo Flota, 1957, Nr 12, pp. 25-32 (USSR)

ABSTRACT: This article is written on the basis of an interview held by the author with Col P.T. Knysh, the commander of a fighter regiment. The views of Col Knysh on military discipline in general and on flight discipline in particular are described by the author. According to the opinion of Col Knysh, every soldier must be firmly convinced that discipline is the decisive factor of all successes both on the ground and in the air. Further, the Colonel relates how the young pilots, after their arrival in the regiment, should be taken care of in every respect, how important it is that the young pilots live together in the officers quarters, and how the commanders must be pedantically exacting toward the young pilots. Three photos appear in this article. The first photo shows the nose part of an aircraft and carries the caption: "On the airfield". The second photo shows

Card 1/2

Flight Discipline

Lt Col V.M. Sinyukayev, Military Pilot First Class. Of him it is said that he had achieved good results in the combat training and in the military and political education of his subordinates. The third photo shows Capt M.V. Kalnyshev, Military Pilot First Class, whom it is said, trained a large number of pilots who became masters of air battles and sniping.

AUTHOR: Kiselev, A.N., Guards Maj.

TITLE: A Difficult Test (Trudnyy ekzamen)

PERIODICAL: Vestnik Vozdushnogo Flota, 1957,⁴⁰ Nr 8, pp.44-48 (USSR)

ABSTRACT: The article, which is presented by the author in narrative form, is apparently intended to acquaint the readers with two phases of the training of pilots in the Soviet air force units: the training of young pilots, and the training for the title of Pilot Class I. As far as the exact sciences are concerned, the article contains no data of any interest. Here below is summarized the rather scarce factual information offered by the author on the two phases of training he deals with. Information referring to the training of young pilots. - During the period of ground training, young pilots get acquainted with the characteristics of the area where the exercise-flights will take place; they also study the details of the materiel they will have to use. - The program of ground training includes the study of the Regulations on Flying and Navigation; special instruction on re-establishing lost orientation is also mentioned. - The normal number of actual exercise-flights the young pilots carry out in the course of their

Card 1/3

86-8-9/22

A Difficult Test (Cont.)

training is much less than the possible maximum. According to the author, when "it was decided to speed up the training", young pilots "have, in a few months, carried out 6 to 7 times more flights than have been carried out during the entire previous year." In describing the training of young pilots, the author touches upon the problem of discipline. In the unit he is concerned with "the discipline is strictly observed" and, as a consequence, "the training, although very intensive, proceeds without accidents". In that connection the author relates that two pilots incurred penalties because, on the eve of exercise-flights, they were absent from their quarters at 11 p.m.; another pilot was punished because in his reports during the flight he tried to conceal the fact that he had lost orientation. Information referring to the training for the title of Pilot Class I

- A pilot cannot start training for the title of Pilot Class I without special authorization from his superior commander.
- In order to obtain the necessary authorization, the pilot concerned must prove that his is an expert group flying, air-combat maneuvering, firing at air and ground targets, and in flying at night and under difficult weather conditions.

TITLE: Starting of the B-3M synchrotron,¹⁹ used as an injector for a positron-electron storage ring 31
B

SOURCE: Atomnaya energiya, v. 20, no. 3, 1966, 206-210

TOPIC TAGS: ^{linear}synchrotron, ~~particle~~ accelerator, storage ring, cyclotron magnet/ VEPP-2 storage ring, B-3M synchrotron, IIL linear accelerator

ABSTRACT: The article describes an adjustment of a synchrotron with external single-turn injector and single-turn emission of electrons and with a specially constructed electromagnet. This pulsed synchrotron is designed to serve as an injector for the VEPP-2 storage ring for colliding positron and electron beams, designed and described by one of the authors (G. I. Budker, et al., in Trudy Mezhdunarodnoy konferentsii po uskoritelyam, Dubna, 1963 [Transactions of International Conference on Accelerators, Dubna, 1963], Atomizdat, 1964, p. 1065, and elsewhere). The article describes the synchrotron itself (Fig. 1), the magnet, two variants of capture into synchronism, and various test procedures. The injector for the B-3M synchrotron was an IIL pulsed linear accelerator. The injected electrons had energy 1 - 1.5 Mev (pulse duration ~7 nsec) and were accelerated to 50 Mev. The B-3M synchrotron makes it possible to

<p align="center">Synthetic CaO-SiO₂-H₂O. Sorption of calcium oxide by silica gel. K. G. Kravchenko and A. V. Kiselev (<i>J. Phys. Chem. Russ.</i>, 1944, 18, 527-529).—The amount of CaO taken up from aq. Ca(OH)₂ by SiO₂ gel within, say, 1 hr. increases with [Ca(OH)₂] (0–45 m-equiv. per l.) according to the usual adsorption isotherm. 1 month later the sorption isotherm has a vertical branch at 3.2 m-equiv. of Ca(OH)₂ per l.; the composition of the solid phase is CaO.SiO₂.aq., and the solution contains 6–7 m-equiv. of SiO₂ per l. At higher [Ca(OH)₂] no equilibrium is reached even within 17 months; probably more basic silicates are formed. Two native forms of hydrated SiO₂ behave like SiO₂ gel. J. J. B.</p>

ADSORPTION OF FATTY ACIDS ON SILICA GEL AND ITS ULTRAPOROSITY. A. V. Kiselev, I. A. Voronov, V. V. Kiseleva, and N. A. Sitokvich, *J. Phys. Chem. (U.S.S.R.)* 10, 83-91 (1948).—The adsorption of AcOH, propionic acid, and stearic acid from CCl_4 at room temp. on SiO_2 gel is less the higher the temp. T of dehydration of the gel. The vols. of AcOH and stearic acid adsorbed at satn. (extrapolated for AcOH) are nearly identical for $T = 485^\circ$ and 800° ; 1 g. of SiO_2 takes up 0.12-0.14 cc. of acid if T was 485° and 0.085-0.082 cc. if T was 800° . Also the eqns. of Bartell and Fu (C.A. 23, 3412) show that the vol. adsorbed is independent of the acid. The "inversion of Traube's rule" observed in the adsorption by SiO_2 gel is due to its ultraporosity, which also makes impossible a calcn. of the specific surface of the adsorbent. For a SiO_2 gel of $T 200^\circ$ which adsorbs a larger vol. of stearic acid than of AcOH this surface is about 3×10^6 sq. cm./g.

<p>The work and heat of adsorption. A. V. Kopylov (Moscow State Univ.). <i>Acta Physicochim. U.R.S.S.</i> 20, 947-99(1945).—The object is a general thermodynamic treatment of the problem of work and heat of adsorption, in which Gibbs' fundamental equations for bulk phases and surface layers are used. Previous expressions were systematized and refined, and new expressions obtained for the integral and differential values of the work and heat of adsorption of gases, vapors, pure liquids, and solns.</p>		<p>Formulas were derived for the work and heat of adsorption, either involving or free from the values of surface tension, which are applicable to liquid and solid interfaces. The work of adsorption depends upon the choice of the initial state of the pure adsorbate or soln.; it differs essentially from the change in surface tension, and equals the latter in some particular cases only. The work (and heat) of adsorption from soln. is equal to the sum of the work (heat) of wetting of ad-sorbent by pure solvent, the work (heat) of adsorption from soln. of the solute and displacement of the solvent by the latter, and the work (heat) of diss. of the soln. A no. of equiv. expressions are given for the differential heat of adsorption corresponding to expts. by calorimetric methods. These expressions involve both isosteric and isobaric or isopycnic temp. coeffs. of equiv. quantities. It is not reasonable to call these equiv. expressions the isosteric and isopycnic heats of adsorption. The differential heats of adsorption of pure substances can be expressed in terms of the isosteric or isopycnic and isothermal coeffs. of surface activity. The formulas, involving isopycnic coeffs., available in the literature, fit only the linear part of the isotherms. The max. work of adsorption, which depends upon the choice of the initial state, must not be confused generally with the adsorption potential. The latter has a definite value under equil. of the adsorption layer with the homogeneous phase, when the thermodynamic work of adsorption is zero. K. H. S.</p>

3931. ACTIVATED CHARCOAL: ADSORPTIVE PROPERTIES AND STRUCTURE.
 Kiselev, A. V. and Shcherbakova, K. P. (Acta Physicochim., U.R.S.S.,
 1976, 21, 539-554).

In studying the structure of solid adsorbents, particularly that of finely porous adsorbents of large absorbing power, consideration must be given to the structure of the solid skeleton, the pores and the interface. The last two features can be investigated by adsorption methods. Investigations have been made over a wide concentration range of the adsorption isotherms of activated charcoal for various organic substances from aqueous solutions. With substance that mix with water, the isotherms pass through a maximum and the total content of the adsorbate in the adsorption volume is much greater than the amount adsorbed. For the homologous series of fatty acids and alcohols, the limiting adsorbed volumes, expressing approximately the volume of the adsorption space, are constant. This rule is accounted for by the complete packing of the charcoal micropores with the molecules of these substances. Changes in the structure of the adsorbate mole-

681. B. M. Kiselev, "Calculation of one-dimensional gas flow" (in Russian), *Appl. Math. Mech. (Prikl. Mat. i Mekh.)*, Jan.-Feb. 1947, vol. 11, pp. 177-192.

The first section of this paper presents a survey of the principles of one-dimensional compressible flow of a perfect gas. The theory of flow with variable cross section, with heat exchange, and with sudden contraction and expansion is developed with reference to static pressure and temperature changes.

These basic principles are applied in the second section to the performance of an ejector. Formulas are developed for the pressure and momentum relationships for compressible flow ejectors. Both subsonic and supersonic flow are considered, omitting, however, any shock phenomena. Newman A. Hall, USA

<p>Thermodynamic properties of adsorption films on silica gel. A. V. Kiselev, N. N. Mikheev, M. A. Romanchuk, and K. D. Bichirbaeva (State Univ., Moscow). <i>J. Phys. Chem. (U.S.S.R.)</i> 21, 1233-34 (1947) (in Russian).—The isotherms of adsorption and desorption of vapors at 14-20° were used for a SiO₂ gel and H₂O, MeOH, and n-heptane. The heat of wetting by evacuated SiO₂ gel was 16.7, 16.7, and 6.5 cal./g. for H₂O, MeOH, and heptane, resp. The specific surface area of the gel was 180-330 sq. m./g. according to the Brunauer-Emmett-Teller method and to the theory assuming the adsorbed film to have the usual surface tension at the start of the hysteresis loop. From the hysteresis loop the most frequent radius of the pores was calculated to be 40-60 Å. The relation between the surface pressure and the work of adsorption was derived. The surface pressure was inversely proportional to the area per mol. as long as this area was large; at higher surface concns. the effects are complicated by the nonuniformity of the surface and by the repulsive forces between the adsorbed molecules. Heat of adsorption from solutions at different temperatures. A. D. Runov, A. V. Kiselev, V. P. Kiselev, and S. N. Alakimov. *Zhur. Fiz. Khim.* 23, 1005-17(1949).—The heat, Q , of wetting fruit-stone charcoal (C.A. 42, 6208c) by $\text{PrOH-H}_2\text{O}$ mixts. was detd. in a calorimeter immersed in a thermostat or in a calorimeter having const. heat exchange (C.A. 43, 6871d); the sensitivity of the latter was 0.01-0.04 cal. but the accuracy of Q was only ≈ 1 cal./g. because of the volatility of PrOH . Q was identical at 25 and 80°; it was 10 for H_2O , and 16, 22, 20, and 20 when the concn. of PrOH was 1, 4, 8, and 12.4 mol./l., resp. The apparent adsorption s of PrOH by C (cf. C.A. 43, 6808c) had a max. near $c = 3$. dQ/dc was pos. at c less than 3 and neg. at c greater than 3. If the total adsorption vol. v is given by $v = -ds/dc$ at c greater than 3, where ds/dc is almost const., the total adsorbed amt. $s = s + v \cdot c$. dQ/ds was 1200 cal./mole at small s , increased with s to a max. at about $s = 6$ millimol./g., and decreased on further increase of s . This decrease may be due to the importance of wide pores at great s , whereas the increase of dQ/ds with s may be due to energy spent on displacing H_2O by PrOH at small s . J. J. Silbermann

Characteristics of Water Sorption With Active Aluminum Oxide
 (Original text in Russian), A. V. Kiselev and E. V. Smirnova;
 J. Phys. Chem. (USSR) Sep '48 (23-9 Monthly); pp 1018-24; 9
 illus, 2 th.

A case is investigated in which the structure of an adsorbent changes in the process of vapor sorption when the structure of the adsorbent appears to be "non-solid." Together with the surface absorption and capillary condensation, the interior of the solid structure is apparently penetrated by the sorption substances. This phenomenon has been observed previously during the sorption of water vapors with montmorillonite clays and egg albumin. The structure of the adsorbent can be "non-solid" in relation to the sorption of given substances, whereas in relation to other substances the adsorbent can behave completely normal, i.e., their adsorption process is not complicated by the far-reaching volumetric absorption. A study of aqueous vapor absorptions with aluminosilicate catalysts has

shown that the desorption side of the isotherm does not coincide with the adsorption side in the entire interval of the vapor pressures; water is firmly retained by these sorbents at a low temperature. In the case of methyl alcohol vapors, the isotherms have a normal aspect for the porous sorbent. A study of sorption-desorption isotherms of water and alcohol vapors in aluminosilica gel specimens and in active aluminum-oxide specimens, obtained through a hydrolysis of aluminum chloride has shown that the absorption of alcohol vapors with these adsorbents is confined to the normal adsorption and capillary condensation. The sorption of water vapors with specimens of aluminosilica gel and active aluminum oxide is accompanied apparently by a very slow process of penetration of the water molecules into the structure of these sorbents.

Adsorption by porous bodies from solutions in the neighborhood of the critical temperature of mixing. The system silica gel-acetic acid-hexane. K. G. Kravtchuk and A. V. Kiselev (Moscow State Univ.). *Doklady Akad. Nauk S.S.S.R.* 66, 817-19(1949); cf. *Chim.* 43, 4636e. Adsorption isotherms of AcOH in soln. in C₆H₆ on a uniformly coarse-pore silica gel, were detd. in sealed tubes, by interferometric analysis, at 45, 30, 20, 8, 4.5, and 0°, i.e. both above and below the crit. temp. of mixing; its position, normally around 20°, varies in contact with the silica gel as a result of its H₂O content, and could only be maintained const. by using a const. proportion of silica gel and vol. of soln. At 45° and 20°, i.e. in the range of unlimited miscibility, the adsorption isotherm is a curve with a max. At 0°, where there are two liquid layers, the isotherm has an upward S-shaped bend. In this case, the coarse pores of the gel are filled as a result of capillary layering. Sorption of AcOH attains at this point 0.2 millimoles/g., this being the excess of the amt. of substance in the adsorption space over that in an equal vol. of the equil. soln. At intermediate temps., the isotherms have an intermediate shape.

General and Physical Chemistry

Structure of silica gels and its effect on adsorption properties. A. V. Kiselev. *Izvestiya i Otkrytiya Khimicheskoy Tekhnologii i Khimicheskoy Khromatografii, Akad. Nauk S.S.S.R., Otdel. Khim. Nauk* 1950, 71-97 (Pub. 1052). — The effects of structure and porosity of SiO_2 gels on adsorptive properties are reviewed, with 53 references. The structural differences are reflected particularly in adsorption of elongated and highly branched molecules. Adsorption isotherms (20° and 40°) for PhOH and MeOH on various SiO_2 gels are reproduced. These permit a ready calculation of the sp. area of SiO_2 gel or quartz powders. G. M. Kosolapoff.

Poisoning and regeneration of the surface of silica gel
in the adsorption of vapors. O. M. Dzhigit, A. V. Kiselev,

N. N. Mikhov-Avgul, and K. D. Shcherbakova (Lomonosov State Univ., Moscow). *Doklady Akad. Nauk S.S.S.R.* 70, 441-4 (1960).—Adsorption-desorption isotherms at 20° and differential heats Q in adsorption and desorption were detd. for MeOH vapor on a homogeneously finely porous silica gel, heated 12 hrs. at 480°, in the relative pressure range $p/p_s = 1.3 \times 10^{-2} - 1.0$, and back to 1.3×10^{-2} in desorption. Q in adsorption and desorption are identical only in the range of capillary condensation; further on, the desorption isotherm lies below the adsorption curve, corresponding to the greater amts. of heat absorbed in desorption as compared with those evolved in adsorption. To eliminate the heat amts. of MeOH, pumping was done over active C, cooled in liquid N₂, with the gel heated to 60°; this left a residue of 0.5 millimole MeOH/g. gel still adsorbed. On repeated adsorption, after heating to 480°, the Q evolved in adsorption were smaller than in the 1st run, and the isotherm lay lower. A further lowering of Q and of the amt. adsorbed occurred in a 3rd run. This cannot be linked with any sintering of the gel which is still stable at 400°, but must be due to a poisoning by MeOH in the absence of H₂O, possibly through formation of superficial ethers of the type

A surface thus poisoned can be regenerated by treatment with H₂O vapor, which hydrolyzes the ethers; after that treatment, Q and the adsorption increase again, attaining values intermediate between those of the 1st and the 2nd series. Repetition of the hydrolytic regeneration operation restores the original Q and adsorption almost completely.

Effect of the structure of the silica gel on the velocity of the sorption of calcium hydroxide from aqueous solutions. O. M. Dabigil, A. V. Kiselev, and K. G. Kravtchenkov (Gosudarst. Vsesoyuz. Nauch.-Issledovatel. Inst. Tsement, Prom. and Moshov, Gosudarst. Univ. im. m.v. Lomonosova). *Doklady Akad. Nauk S.S.S.R.* 71, 77-9

(1960).—The aunts. of $\text{Ca}(\text{OH})_2$, in mg.-equiv./g., sorbed from a clear aq. soln. after a stated length of time (1 hr. to 30 days), are plotted against the concn. of the soln. after sorption. The isotherms are substantially different for a coarsely-porous silica gel (I), characterized by marked capillary condensation and considerable hysteresis in the sorption of $\text{Ca}(\text{OH})_2$ vapor at 20° , and a finely-porous silica gel (II) showing no capillary condensation under the same conditions. Pore vol. distribution curves show, for II, a sharp peak at about 10 A., and in the range of 80-100 A. for I. Sorption of $\text{Ca}(\text{OH})_2$ was detd. with fractions of I and II remaining after sifting with 10,000 mesh/sq. cm., and heated 4 hrs. at 350° . All points of the isotherms corresponding to the same initial concn. lie on the same straight line which connects the point on the axis of abscissas expressing the original concn. of the soln. with the point on the axis of ordinates corresponding to complete extr. of all $\text{Ca}(\text{OH})_2$ from the soln. In the case of I, the 1-hr. isotherm shows irregularities of shape indicative of vol. sorption. Isotherms taken at later stages become increasingly straightened out; the 24-hr. isotherm is very nearly vertical, and, after 30 days, it corresponds to the equil. between the initial silica gel SiO_2 -aq., the silicate $\text{CaO} \cdot \text{SiO}_2$ -aq., and the aq. soln. The coarse pores of I permit ready diffusion of $\text{Ca}(\text{OH})_2$, and the Ca silicate formed does not prevent its access to the surface of yet unreacted SiO_2 . This is not so in the case of II. All isotherms, including that taken after 30 days, show the familiar shape of initial rise and leveling off, and lie very closely one above the other. Sorption after 30 days is only a little greater than after 1 day.

Absolute heats of wetting of barium sulfate by water and by alcohols. B. V. D'ya, A. V. Kiselev, V. P. Kiselev, O. A. Likhacheva, and K. D. Nizhnikova (Moscow State Univ.). *Doklady Akad. Nauk S.S.S.R.* 73, 827-30 (1980).
Calorimetric data were made on 2 samples of BaSO₄, one of sp. surface area 7 sq. m./g. (I), the other 9.7 sq. m./g.

(II), weighed at 400 and 300°, resp. (at the lower temp. for the finer-grained II, to avoid sintering). The exptl. values, at 20°, are, on I, H₂O 0.78 ± 0.03, MeOH 0.36 ± 0.005, BuOH 0.88 ± 0.08 cal./g.; on II, H₂O 1.07 ± 0.08, MeOH 0.81 ± 0.006, EtOH 0.80 ± 0.01, PrOH 0.80 ± 0.01, BuOH 0.79 ± 0.08, C₆H₅OH (at 20°) 0.81 ± 0.01, C₁₂H₂₅OH (at 20°) 0.79 ± 0.01. The values for all the alcs. are practically identical, i.e. the chain length has no effect on the heat of wetting; on the other hand, the heats of wetting for H₂O and for the alcs. are distinctly different. The data recalcd. for equal surface area, are (av. of I and II), H₂O 455, alcs. 385-390 ergs/sq. cm. N. Thon

Inst of Phys, Moscow State U imeni M. V. Lomonosov

"Zhur Fiz Khim" Vol XXV, No 6, pp 710-718

Investigated adsorption of N_2 vapors at bp on uniform coarsely porous silica gel over range of relative pressures from 10^{-6} to 0.5. Adsorption isotherms were reproducible for entire region. At low pressures equil was attained very slowly. No straight-line "Henry region" was found. Sp surface was detd by different methods with closely corresponding results. For range of filling of surface from 20 to 90% isotherm corresponds to 1st ep of M. M. Dubinin and L. V. Radushevich, for greater deg of filling to eq of W. D. Harkins and G. Jura. In latter case 2d layer of adsorbed N_2 mols is formed.

"Dok Ak Nauk SSSR" Vol LXXVI, No 6, pp 855,858

Adsorption isotherms of benzene, heptane, and MeOH were taken on uniform roughly porous silica gel (structural type 2). Found surface of adsorbed film to be equal to surface of the adsorbent and not to depend on nature of vapor. Detd distribution of vol of pores by structure-adsorption method, method of pressing Hg into the pores, and electronic microscope method. Results obtained by the 3 methods checked.

On- and multimolecular adsorption from solution on a nonporous adsorbent. A. Y. Kiselev and K. G. Krasil'nikov (Moscow State Univ.), *Doklady Akad. Nauk S.S.S.R.* 77, 1021-4 (1961).—Adsorption isotherms from solns. of PhOH in C₁₁H₂₃ on BaSO₄ powder of sp. surface area 0.7 sq. m./g. were detd. at 20°, where soln. leads to crystn. of PhOH, and at 40° where soln. results in sepn. into 2 liquid layers. At 20°, the isotherm levels off at a relatively low concn., 28 millimole/l. (i.e. 0.1 of satn.) and the adsorption remains practically unchanged up to satn. of the soln. and beyond it. This const. adsorption, 58 millimole/g., corresponds to a surface area of 28 Å²/mol. PhOH; consequently, under these conditions, only one close-packed unimol. adsorption layer is formed. At 40°, the isotherm is S shaped, beginning to rise at approx. a relative concn. $c/c_s = 0.6$ ($c_s = 1.3$ mole/l.). From this point on, adsorption is multimol., but the thickness of the adsorbed layer does not exceed 2-3 mole. even at $c/c_s = 0.9$. A similar isotherm is found with MeOH in C₁₁H₂₃ on BaSO₄. N. Thon

KISELEV, A.V.

1951

Absolute adsorption isotherms from solution. K. G. Krasil'nikov and A. V. Kiselev (Moscow State Univ.). *Doklady Akad. Nauk S.S.S.R.* 77, 1047-50 (1951); cf. Argul, et al., *C.A.* 45, 6483g. Adsorption isotherms were detd. for solns. of PhOH in $C_{12}H_{18}$ at 20° and 40°, on the highly coarse silica gel "E" (I), the coarse silica gel "VK-Kh-2" (II), a relatively fine-pore silica gel "No. 45" (III), and nonporous $BaSO_4$ (IV). Total pore vol. in cc./g., most frequent pore diam. in Å., and sp. surface area s in sq. m./g. were: for I 1.72, 260, 320; II 0.92, 90, 350; III 0.53, 30, 600; IV —, —, 9.7. At 20°, satn. in the vol. results in crystn., and at 40° in sepn. into 2 liquid layers. The isotherm on I at 20° has the normal shape up to satn., whereas at 40° it is S-shaped. Plots of the amt. of PhOH adsorbed, a , per unit sp. surface area, S , as a function of its concn., c , at 20°, coincide for I, II, and III; consequently, the porosity of the silica gel shows no effect on the adsorption up to a pore size of 30 Å. Near satn., $a/s =$ micromole/sq. m., which gives $s/a = 26$ Å.²/mol. PhOH, i.e. adsorption at 20° remains unimol. up to satn. Conversely, adsorption of PhOH from soln. in $C_{12}H_{18}$ can be used to det. the unknown sp. surface area of a silica gel. On IV, adsorption is still unimol., but the limit is reached at about $c = 0.1$ *c*_{sat}. Plots of a/s at 40°, on I, II, and IV, are still S-shaped, with the isotherms coinciding only in their initial portions but diverging beyond the initial stage. This divergence is the result of multimol. adsorption on IV, but is due to capillary layering in the case of the silica gels; the latter effect is more pronounced, the larger is the pore vol. That the rise of a/s on coarse silica gels at higher concn. is not due to mere multimol. adsorption, or to layering in the space between grains, follows from the fact that in the range of relative concns. 0.7-1.0, a/s is much greater, and rises more steeply with c , for the silica gels than for IV. Consequently, the effect consists in capillary layering, analogous to capillary condensation of vapors. At $c/c_s = 1$, I adsorbs 10-17 millimoles PhOH per g., or 1.5 cc. liquid PhOH/g. This, with some $C_{12}H_{18}$, is sufficient for complete filling of the pore vol.

"Dok Ak Nauk SSSR" Vol LXXIX, No 3, pp 451-455

Detailed study by the vacuum method was made of the adsorbed quantities, the isotherms of sorption and desorption of vapors of benzene, n-pentane, n-butanol, and methanol at 20° C and of water vapor at 25° C on 2 activated carbon samples which differed greatly in structure (monodisperse micropores as compared with large pores). The findings are shown in tables and graphs. It is hoped that a more rigid analysis of desorption curves will yield a more exact idea of the pore structure of activated carbon.
